

Git commands

Fork	a copy of the repository to your Github account
Clone	downloading the repository from a remote server to your local computer
Branch	a parallel version of the repository
Master / main	the main or primary branch of the repository
Commit	is like saving the current state of the project in a version control system
Pull	get all the changes made since the last synchronization with the remote repository
Push	to send the latest version of the project to your repository
Merge	merging changes from a repository branch with the main repository branch or merging changes from one repository branch with any branch of the same repository

Github flow in your repository

Create a branch from main	When you start working on new code, you create a new branch in the repository. In this branch, you will make your changes.
Add changes (commit)	You add, edit, and delete files in your branch. Each change is called a commit. You can make many commits until you finish your work.
Send a pull request	When ready to share your changes, you create a pull request — like proposing changes to the main code branch.
Discuss and make edits (code review)	During the pull request discussion, you may get comments and suggestions for improvement. You can make edits until everything is ready.
Merge changes	When your pull request is ready, you can merge your changes with the main code branch. This way, your code becomes part of the project.
